CS 6240 – Parallel Data Processing with Map Reduce Section-01, HW-4, Biyanta Vipulbhai Shah

Design Discussion

Describe the steps taken by Spark to execute your source code. In particular, for each method invocation of your Scala Spark program, give a brief high-level description of how Spark processes the data

The data is read and referenced from (http://spark.apache.org/docs/latest/programming-guide.html)

SparkContext object coordinates the sets of Spark processes running on a cluster in your main program. On a particular cluster, the SparkContext connects to several types of cluster managers (in our case STANDALONE or YARN), to allocate resources across applications. Once connected to these clusters, Spark obtains the executors on nodes in the cluster, these are processes that run the computations and store data. It next, sends the application code (JAR files in our case) to the executors. Finally, SparkContext sends tasks to the executor to run.

	High level description of Spark
Method Invocation	processing
map	Returns a new RDD, by implementing a
•	function to all the elements of the RDD.
filter	Returns a new RDD which contains only
	elements that satisfies the condition.
flatMap	Return a new RDD which flattens all the
	elements of this RDD.
keyBy	Creates tuples of the given RDD, by applying
	the specified function. When called on
	RDD[(K,V)] it converts into tuple, with the
	given function. Then K and V can be
	accessed as tuple1 and tuple2.
join	When called on RDD[(K,V)] and
	[RDD[(K,W)], returns a $[RDD[(K,(V,W))]$
	pairs with all pairs of elements for each key
reduceByKey	When called on a RDD[(K, V)] pairs, returns
	an RDD[(K, V)] where the values for each
	key are aggregated using the given reduce
	function func, which must be of type (V,V)
	=> V
subtractByKey	Returns an RDD with the pairs from an RDD,
	whose keys are not present in the other RDD.
union	Returns a new RDD, which contains
	elements in the source RDD and the one
	given in the argument.

mapValues	Returns a new RDD which performs function
	on only the values of the RDD. (map
	performs the function on the keys as well as
	the values in the RDD)
takeOrdered	Returns the first n elements of the RDD using
	either their natural order or a custom
	comparator.
reverse	Reverses the string column and returns it as
	a new string column

Compare the Hadoop MapReduce and Spark implementations of PageRank

• For each line of your Scala Spark program, describe where and how the respective functionality is implemented in your Hadoop jobs.

Spark Execution	Hadoop Execution
<pre>var pagesWithoutTilde = sc.textFile(inputFile, sc.defaultParallelism) .map(record => Bz2WikiParser.parseXML(record)) .filter(record => !record.contains("tilde record")) .map(record => record.split("BIYANTA")) .map(record => if(record.length == 1) {</pre>	The file where this functionality is implemented in Hadoop is PageRankPreProcess.java Map: Gets the data from the Bz2 parser. Returns a custom object which contains the node and its out-links. If the node does not have any out-links (dangling nodes), it returns an empty list. Reduce: Converts out-links into strings, and adds page rank = -1.0 (which shows that page rank still has not been calculated)
<pre>val totalRecords = finalPages.count() val initialPageRank: Double = (1.0 / totalRecords) val alpha: Double = 0.15 var finalPagesWithRanks = finalPages.keys.map(record => (record,initialPageRank))</pre>	The file where this functionality is implemented in Hadoop is PageRankCalculate.java and PageRankFinalDeltaCalc.java It gets its input from PageRankPreProcess.java output.

```
for (i <- 1 to 10) {
 try{
  var danglingMass = sc.accumulator(0.0)
  var pageRankCalc =
finalPages.join(finalPagesWithRanks).values
   .flatMap {
    case (outLinks, pageRank) => {
      val size = outLinks.size
     if (size == 0) {
      danglingMass += pageRank
      List()
      else {
      outLinks.map(link => (link, pageRank / size))
   }.reduceByKey( + )
  pageRankCalc.first()
  val delta : Double = danglingMass.value
  var one =
finalPagesWithRanks.subtractByKey(pageRankCalc)
  var two = one.map(page =>
(page. 1,0.0)).union(pageRankCalc)
  finalPagesWithRanks =
two.mapValues[Double](accumulatePageRank => (alpha /
totalRecords
   + (1- alpha) * (delta / totalRecords +
accumulatePageRank)))
```

Map: Assigns initial page rank in the first iteration. Emits each node and its adjacency list and page rank. For dangling nodes emits the "dummy" key and the page rank. Also emits the P(m)/C(m) calculation for each page in the outlinks. The Map also updates the page ranks by adding the delta values for iteration i in iteration i+1.

Reduce: Calculates the delta, by the page ranks of the dangling nodes and does an intermediate calculation of page ranks without the dangling node mass value.

Since the page ranks are updated in iteration i+1 for iteration i, we will need an extra map job to just compute the final updated page ranks for iteration i. This computation is done in PageRankFinalDeltaCalc.java

The Driver program is from where the PageRankCalculate.java is iterated over 10 times.

```
var sorted =
finalPagesWithRanks.takeOrdered(100)(Ordering[Doub
le].reverse.on { line => line._2 })
```

var finalTopK =
sc.parallelize(sorted).saveAsTextFile(outputFile)

The file where this functionality is implemented in Hadoop is PageRankTopK.java

It gets its input data from PageRankFinalDeltaCalc.java output.

Map: Computes the local top 100 for page ranks.

Reduce: Combines all these local top 100 records and generates

global top-100 page ranks with its
pages.

• Discuss the advantages and shortcomings of the different approaches. This could include, but is not limited to, expressiveness and flexibility of API, applicability to PageRank, available optimizations, memory and disk data footprint, and source code verbosity.

Comparison Measures	Spark	Hadoop
Memory and disk data footprint	Spark processes data-in-memory. Thus Spark needs a lot of memory. If data is too big to fit into memory, then there would be performance degradation. Hence a lot of memory is used but since we do not keep writing to the disk, disk data footprint is less.	Hadoop MapReduce persists back to the disk after a map or reduce action. It kills a job as soon as it is done. Thus less memory is used. However we write to and fro to HDFS for iterative computations, thus increasing the disk data footprint.
Expressiveness and flexibility of API	Spark has comfortable APIs for Java, Python and Scala, hence having increased flexibility for API than Hadoop. Spark also has an interactive mode for running commands making it more expressive as well.	Hadoop MapReduce is written in Java and is infamous for being very difficult to program. Although it has tools to make it easier. Map Reduce does not have an interactive command line, being less expressive for its users.
Source Code Verbosity	Spark code is very concise .	Hadoop MapReduce code will be high in verbosity
Cost	Since the Spark needs data to fit into the memory, if the memory in the Spark cluster is at least as large as the data we need to process, then it'll be the cheaper option.	If the cluster isn't as big as the data is, then Hadoop MapReduce would be the cheaper option since hard disk is quite cheaper than memory space.
Applicability to Page Rank	Spark is applicable to Page Rank	Hadoop as well is applicable to Page Rank. The difference between the two would be the trade-offs explained in point 1, 2 and 3. The programmer can take those points into consideration and choose a framework.
Fault Tolerance	Spark has several retries per task, however since it relies on memory, when Spark program fails, it needs to start processing from the start.	Hadoop MapReduce also has several retries per task, but MapReduce relies on hard disk, so if a process fails then it could start it from where it failed, thus saving time. Hadoop would thus be more fault tolerant than Spark.

Performance Comparison

Run #	Spark Execution Time	Hadoop Execution Time
Run - 1 (5 worker machines)	6454 seconds	3868 seconds
Run - 2 (10 worker machines)	2722 seconds	2287 seconds

Discuss which system is faster and briefly explain what could be the main reason for this performance difference.

According to my understanding and readings done from the modules, since Scala is better for iterative computation due to less writes on HDFS, it should be faster. However, as you can see from the above comparison, such is not the case.

One reason could be that I am not able to efficiently understand how RDD's are persisted and thus am not making correct design decisions, also partitioning, reduce and map methods may be used incorrectly, hence slowing down the process.

Also another plausible explanation for this could be, when we are parsing the compressed bz2 file; Spark, by default might not be parallely processing the parser written in Java, since preprocessing the input file is a major chunk of the data load, the same could be causing delays in the total execution time. I have tried to optimize the code and run it to the best of my abilities and understanding.

Spark Execution:

Output of the simple Wikipedia data set on local machine (standalone mode)

Are the results the same?

Yes, the results for Spark and Hadoop execution are the same.
